Evaluation: Does conformance information derived from a process model improve the prediction of future deviations and compliance risks?

Group 4:
Richard Schuppener, Cem Colak

Contents

1 Experimental Study

1. A clear definition of the prediction problem and label construction: for example, defining a case as "deviant" if its final alignment cost exceeds a chosen threshold, if a particular rule is violated (e.g., an LTL constraint), or if conformance checking detects a specific type of non- compliant pattern. Motivations for the chosen definition must be documented.

2 Example Dataset

3

4 Sprint review

4.1 Richard Schuppener

5 Content for the evaluation

Lab Evaluation Report: deliverables and content

1 Definition of the prediction problem and label construction for conformance deviation targets

explaining both technical details and conceptual implications for organizations that wish to anticipate and mitigate non-compliant behavior.

2 Choosing dataset for the prediction problem

3 definition of the dedicated CLI walkthrough -¿ Maybe 2-3 cases which are based on prefix length

4 evaluation protocol: How will the data be processed and what splitting etc. is applied and why exactly that

5.1 Application of Baseline Model

5.2 Application of Conformance-aware model (which may augment the results) -¿ Clearly state the chosen parameters and why they were chosen for the specific usecase

6 Evaluate the target with the evaluation module's outputs.

7 COMPARISON: baseline/conformance target predictions -¿ Usage of visualizations and metrics

Discussion on computational aspects: Measure, reporting of runtime, feasability -¿ mention the conformance deviations -¿ mention that if prefix-generation with rising length makes the whole process taking much more computational power

8 General discussion: -¿ does it improve predictions using conformance features? -¿ Which indicators are useful -¿ threats to validity? ——¿ Mention alignment noise, multiple target labels for one case, definition of labels, missing labels for cases, bad data quality, highly individual data, -¿ limitations and Ideas to future work
